

PROCESS

The project began with a series of speculative experiments exploring different future scenarios through short Blender animations. These ranged from childhood fears and peripheral hallucinations to the possibility of sound travelling through space and shaping future religions. While each concept investigated atmosphere and perception, research into long-term nuclear waste warning messages became the foundation of the final project.

Rather than designing another visual marker, I explored whether sound could function as a warning across millennia. Unlike language, which continuously evolves, certain auditory experiences—such as irregular heartbeats, sudden silence, harsh frequencies, and instinctively unsettling sounds—may continue to evoke a physical response even if their original meaning is forgotten. This idea formed the basis of an original soundscape intended as an alternative long-term warning system.

The accompanying animation places the viewer inside a vast spike field, one of the proposed physical markers for nuclear waste repositories. Presented from a first-person perspective, the animation follows a disoriented figure wandering through an endless desert as sandstorms, oppressive sunlight, and the persistent warning sound create an overwhelming sensory experience. Rather than offering a narrative resolution, the animation loops indefinitely, suggesting an environment from which there is no escape.

The work was presented as an installation within a darkened room. The animation was projected onto a semi-transparent screen while the soundscape played at an intentionally uncomfortable volume. Standing beside the projection caused the moving image to spill onto both the viewer and the surrounding walls, creating the impression of movement within the viewer's peripheral vision and extending the experience beyond the screen. The complete environment was designed to communicate danger through atmosphere and instinct rather than language.
